

Kaiaulu Executables: : CHEAT SHEET

About

Executables provide access to Kaiaulu's functions through a command line interface. This allows other tools to build on Kaiaulu capabilities or use it server-side.

Project Config Setup

The first part of running any vignette is setting up your project configuration file (examples in /conf).

Required Fields

- **mailing_list:** ...
- **issue_tracker:** ...

Analysis Config Setup

An analysis file is also required to specify filters and parameters.

Required Fields

- **filters:** ...
- **analysis:** ...

Tools Config Setup

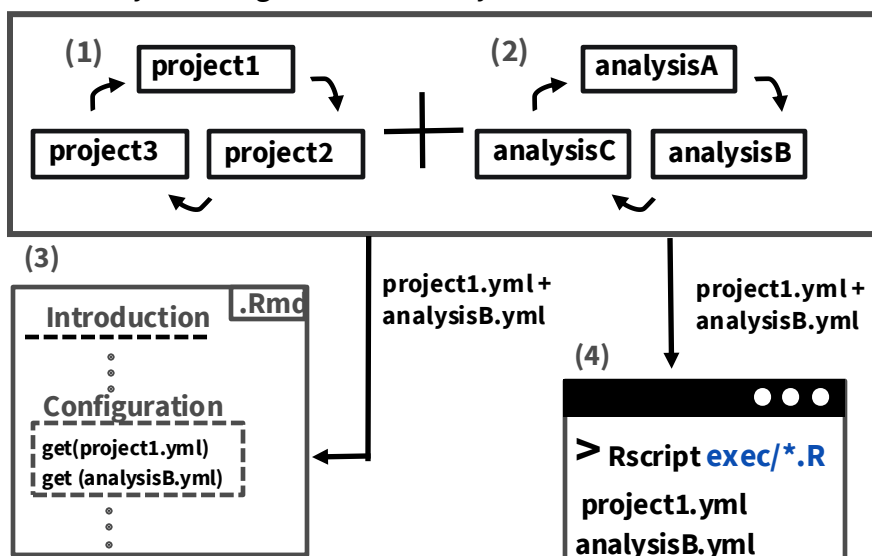

The required external tools must be specified in tools.yml.

Required Fields

- **perceval:** ...

Exec Configuration

Executables require configuration files to find information about the project, analysis parameters and tools needed. The project and analysis config are also used by notebooks in Kaiaulu.

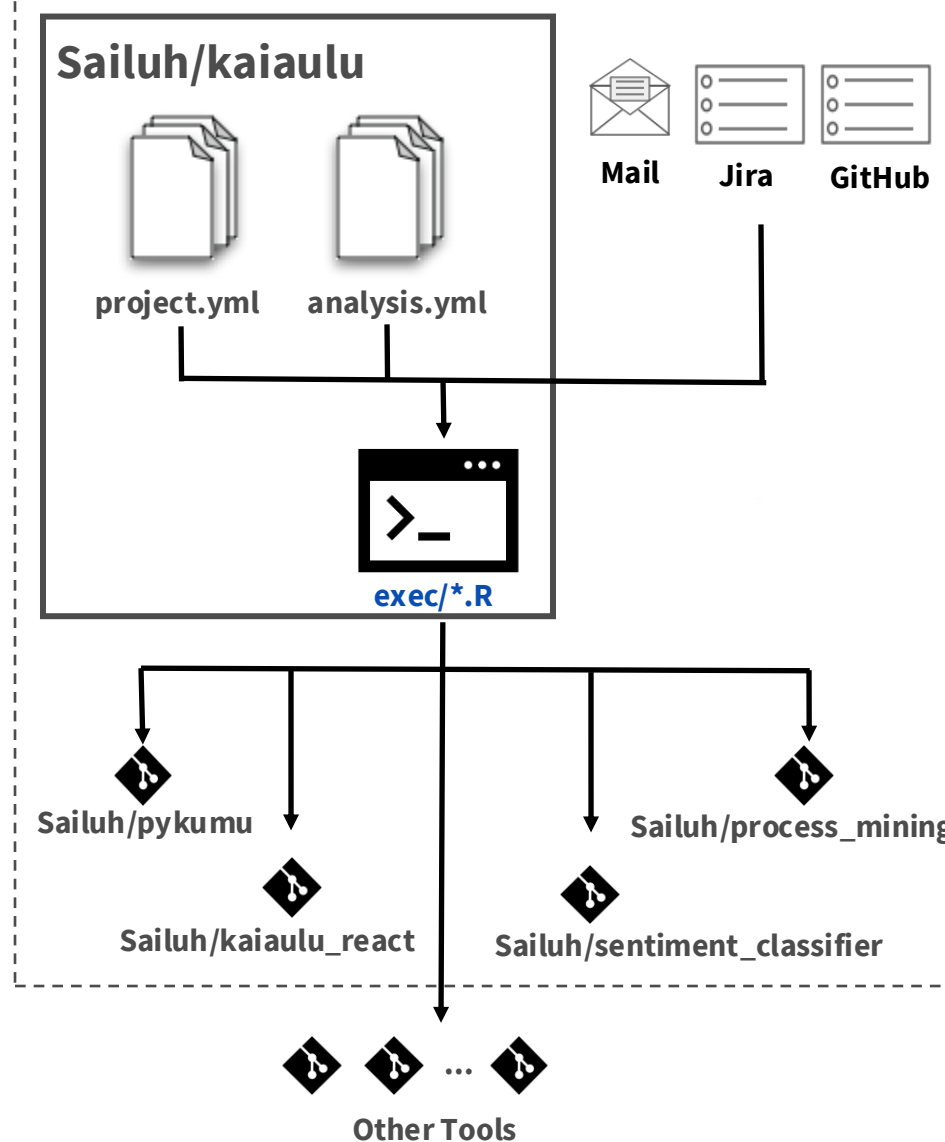

Interchangeable Configurations

Any project.yml files (1) can be combined with any analysis.yml files (2). This allows users to run the same analysis on multiple projects or run different analyses on the same project, reducing duplication of configuration sections. See Configuration (.yml) cheatsheet for more information.

Data Extraction

Sailuh tools in tools.yml rely on kaiaulu executables to download and refresh data. Kaiaulu executables also expose capabilities to other tools outside of the sailuh ecosystem.

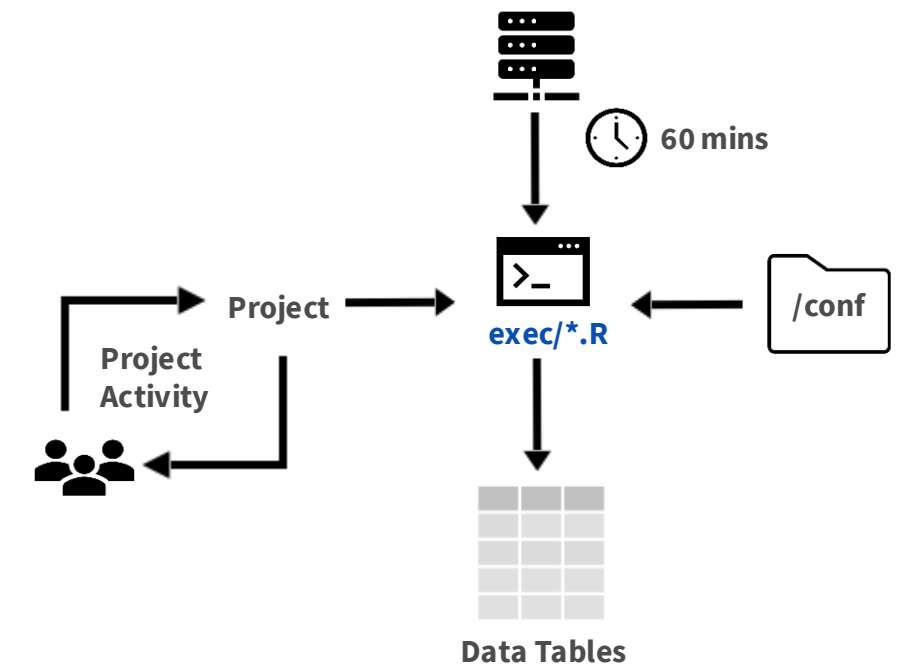

Sailuh

Kaiaulu executables provide data from sources such as Mail, JIRA, GitHub, and other analyses, including social smells.

Server Side Execution

Cron jobs can be used to call executable download scripts every x minutes (E.g., 60 minutes) using the refresher API. This can be combined to the sailuh/kaiaulu_react to monitor project health or create data warehouses.

Data Pipelines

Executables can also be chained together to construct more complex pipelines. By using different combinations of project.yml and analysis.yml files, this can facilitate extending data pipelines, much like chaining commands in bash.
